# NFA with epsilon transitions

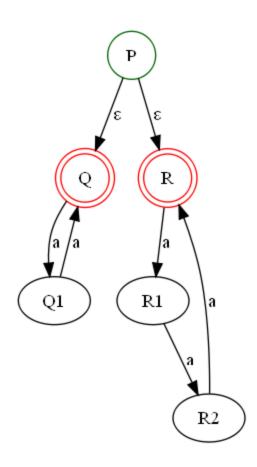

Sipser pages 47-54

### NFA's with $\varepsilon$ –Transitions

- We extend the class of NFAs by allowing instantaneous (ε) transitions:
  - 1. The automaton may be allowed to change its state without reading the input symbol.
  - 2. In diagrams, such transitions are depicted by labeling the appropriate arcs with  $\varepsilon$ .
  - 3. Note that this does not mean that ε has become an input symbol. On the contrary, we assume that the symbol ε does not belong to any alphabet.

# example

• { a<sup>n</sup> | n is even or divisible by 3 }

#### Definition

• A  $\epsilon$ -NFA is a quintuple  $\mathbf{A}=(\mathbf{Q}, \mathbf{\Sigma}, \mathbf{\delta}, \mathbf{q}_0, \mathbf{F})$  where

- -Q is a set of states
- $-\Sigma$  is the alphabet of input symbols
- $-\mathbf{q}_0 \in \mathbf{Q}$  is the initial state
- $-\mathbf{F} \subset \mathbf{Q}$  is the set of *final states*
- $-\delta: \mathbf{Q} \times \Sigma_{\epsilon} \longrightarrow \mathbf{P}(\mathbf{Q})$  is the transition function
- Note  ${f E}$  is never a member of  ${f \Sigma}$
- $\Sigma_{\mathbf{\epsilon}}$  is defined to be  $(\Sigma \cup \mathbf{\epsilon})$

#### ε-NFA

 ε -NFAs add a convenient feature but (in a sense) they bring us nothing new: they do not extend the class of languages that can be represented. Both NFAs and ε-NFAs recognize exactly the same languages.

- ε-transitions are a convenient feature: try to design an NFA for the even or divisible by 3 language that does not use them!
  - Hint, you need to use something like the product construction from union-closure of DFAs

### ε-Closure

- ε-closure of a state
- The  $\epsilon$ -closure of the state q, denoted ECLOSE(q), is the set that contains q, together with all states that can be reached starting at q by following only  $\epsilon$ -transitions.

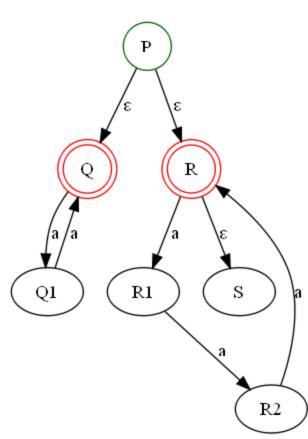

- In the above example:
- ECLOSE(P) ={P,Q,R,S}
- ECLOSE(R)={R,S}
- ECLOSE(x)={x} for the remaining 5 states {Q,Q1,R1,R2,R2}

# Computing eclose

 Compute eclose by adding new states until no new states can be added

- Start with [P]
- Add Q and R to get [P,Q,R]
- Add S to get [P,Q,R S]
- No new states can be added

### Elimination of ε-Transitions

- Given an ε-NFA N, this construction produces an NFA N' such that L(N')=L(N).
- The construction of N' begins with N as input, and takes 3 steps:
  - 1. Make p an accepting state of N' iff ECLOSE(p) contains an accepting state of N.
  - 2. Add an arc from p to q labeled a iff there is an arc labeled a in N from some state in ECLOSE(p) to q.
  - 3. Delete all arcs labeled ε.

### Why does it work?

 The language accepted by the automaton is being preserved during the three steps of the construction: L(N)=L(N<sub>1</sub>)=L(N<sub>2</sub>)=L(N<sub>3</sub>)

 Each step here requires a proof. A Good exercise for you to do!

### Theorem

Any NFAe can be turned into an NFA

• How?
